Introduction

WHO 2010 divided man infertility into 3 groups: normozoospermia (sperm concentration >=15 billion/ml), oligozoospermia (sperm concentration < 15 billion/ml) and azoospermia (no sperm) [1]. There are many studies determined seminal fructose and its correlations with sperm concentration, vitality and motility (progressive). Besides, these studies also showed the reason of man infertility cases which azoospermia and no seminal fructose. Materials and methods: Include random 60 normozoospermia, 60 oligozoospermia semen. Determine fructose concentration by ROE method. 25 azoospermia cases with no fructose had been examined and proceed percutaneous epididymis sperm aspiration (PESA) to find the infertility reason.

Materials and Methods

The studies select semen of infertility men (age 18-50) visited in Centre of genetics counselling of Hanoi medical university hospital from 3/2017 – 5/2018. After analyzing the semen, results of sperm concentration, vitality and motility were selected. Random choose 60 normozoospermia cases and 60 oligozoospermia to determine seminal fructose concentration by ROE improved method [12]. Fructose content in seminal plasma was determined in examination of obstructive azoospermia and inflammation of male accessory glands [8,9]. The role of fructose concentrations in seminal plasma of patients with oligozoospermia and azoospermia did not decrease as compared to normal men.

Abstract

Background: This is a review from 2 studies that determine the concentration of seminal fructose and show the correlations between seminal fructose concentration with sperm concentration, vitality and motility (progressive). Besides, these studies also show the reason of man infertility cases which azoospermia and no seminal fructose. Materials and methods: Include random 60 normozoospermia, 60 oligozoospermia semen. Determine fructose concentration by ROE method. 25 azoospermia cases with no fructose had been examined and proceed percutaneous epididymis sperm aspiration (PESA) to find the infertility reason.

Results: Fructose concentration of normozoospermia: 1.601 ± 0.604 (g/l) significant lower than oligozoospermia: 1.881 ± 0.640 (g/l). Fructose seminal concentration has negative correlations with sperm concentration (R = -0.156; p > 0.05); sperm vitality (R = -0.065; p > 0.05); sperm progressive motility (R = -0.186; p < 0.05). Examine and process percutaneous epididymis sperm aspiration (PESA), 25 azoospermia with no fructose cases have diagnosed congenital bilateral absence of the vas deferens (CBAVD).

Conclusions: Seminal fructose concentration of normozoospermia group is significant lower than oligozoospermia group. Fructose seminal concentration has negative correlations with sperm concentration, concentration and motility. 100% azoospermia cases with no seminal fructose have diagnosed CBAVD.

Keywords: Infertility; Seminal Fructose; Azoospermia; CBAVD

Abbreviations: CBAVD: Congenital Bilateral Absence Of The Vas Deferens; PESA: Percutaneous Epididymis Sperm Aspiration; HCl: Hydrochloric Acid
by the resorcinol method where fructose reacts with resorcinol in concentrated hydrochloric acid (HCl) solution to form a red compound. Measure the coloric complex of Zinc and Fructose at a wavelength of 560 nm against blanks. Besides, 25 patients that azoospernia with no fructose had been examined and proceed percutaneous epididymis sperm aspiration (PESA) to find the infertility reason in Andrology Department, Hanoi Medical University Hospital. Use SPSS version 16.0 to analyze the results.

Results and Discussion

Abdella MA [13] have reported that seminal fructose concentration is higher in oligozoospermia and lower in azoospermia and asthenospermia [13]. Fructose concentration in normozoospermia is significant lower than oligozoospermia [14]. Table 1 and Figures 1-3 shows that seminal fructose in oligozoospermia is significant higher than oligozoospermia (p<0,05). Besides, other semen characteristics include sperm concentration, vitality and progressive motility in oligozoospermia are significant lower than normozoospermia (p<0,001). That means when seminal fructose decreases, sperm concentration, vitality and progressive motility increase. In some cases that sperm count and sperm concentration are too high, seminal fructose may decrease lower than normal. To clear these correlations between seminal fructose and other semen characteristics, the studies analyze selected results by Pearson’s correlation. The results show the negative correlations between seminal fructose and sperm concentration (R = -0,156 and p>0,05), sperm vitality (R = -0,065 and p>0,05) and sperm progressive motility (R = -0,186 and p<0,05). Gonzales GF [15], Orakwe JC [16] and Mahmoud HH [17] have reported similar conclusions. Fructose in semen is the source of energy of every sperm activities. The higher of sperm concentration, vitality and motility asked for more energy, so fructose is lower [18,19]. The study of Lu (2007) reported when sperm motility increased, fructose decreased and in vitro, sperm continued using fructose [18].

Normal seminal fructose concentration confirms the role of testosterone and the function of vesicles and vas deferens are normal [20]. The absence of both sperm and fructose correlates with the obstruction in CBAVD or retrograde ejaculation [1,21]. Especially, the correlation between azoospermia and fructose in CBAVD had been proved by many authors [22]. All 25 cases azoospermia with no seminal fructose had been examined and proceed percutaneous epididymis sperm aspiration (PESA) by andrologies to find the infertility reason. The result shows that the reason in all the cases is CBAVD. Fructose concentration in obstructive azoospermia cases is lower than normal or zero [23]. By other side, non-obstructive azoospermia, fructose concentration

usually higher or equal than normal [21]. Inflammation of the reproductive glands causes temporary obstruction, so that sperm count and seminal fructose concentration may decrease, but rarely absence both of them [21,24].

Follow to WHO 2010 [1], Gonzales G F [15], Kumar R [4], some characteristics of the semen in obstructive infertility include:

a. Azoospermia.
b. Seminal fructose low or zero.
c. Volume of semen < 1.5ml.
d. pH of semen < 7.

Our studies show that all 25 azoospermia cases with no seminal fructose are CBAVD. Because of that reason, seminal fructose test is considered to replace epididymis sperm aspiration (PESA) to find the infertility reason. Fructose is a main carbohydrate source in seminal plasma and necessary for sperm motion [25,26]. The measurement of seminal fructose has been used in most laboratories. Therefore, the World Health Organization manual recommends measurement of seminal fructose as a marker of seminal vesicular function [27]. Methods for determination of seminal fructose mainly include gas chromatography, indole coloration, and resorcinol coloration. In particular, the resorcinol method has been used widely in clinical andrology laboratories for its simplicity of operation, high specificity, and no need for special instrument. Fructose in semen is the source of energy for all sperm activities. The higher of sperm concentration, vitality and motility asked for more energy, so fructose is lower [7,28]. Normal seminal fructose concentration confirms the role of testosterone and the function of vesicles and vas deferens are normal [29].

In this study, negative correlations were observed between seminal fructose and sperm concentration (R = -0.156 và p<0.05), sperm vitality (R = -0.065 và p<0.05) and sperm progressive motility (R = -0.186 và p<0.05). This finding is in line with that of Gonzales GF [11], Orakwe JC [30] and Mahmoud HH [31]. Fructose in semen is the source of energy for all sperm activities. The higher of sperm concentration, vitality and motility are inversely ratio to sperm motility with R = -0.21 with correlation was significant at 0.05 level [35]. Fructose is the major glycolysable substrate of seminal plasma and is widely accepted as a marker of seminal vesicle function [34-36]. Inflammation may lead to atrophy of the seminal vesicles and low seminal fructose concentration. When ejaculatory ducts are blocked, fructose concentration in seminal plasma usually decreases and may become undetectable [34,37]. Additionally, seminal plasma fructose concentration determination is useful for auxiliary diagnosis of obstructive and nonobstructive azoospermia. Seminal fructose concentration in non-obstructive azoospermia is usually higher than or equal to that in males of normal fertility [33]. However, fructose concentration in seminal plasma of patients with obstructive azoospermia is usually absent or significantly lower than that in men of normal fertility [34,36]. Absence of seminal fructose has also been found in patients with congenital vas deferens-seminal vesicle developmental defect [39]. Therefore, our results are consistent with most of the results of studies in the world.

Normal seminal fructose concentration confirms the role of testosterone and the function of vesicles and vas deferens are normal [36]. The absence of both sperm and fructose correlates with the obstruction in CBAVD or retrograde ejaculation [9,13]. Especially, the correlation between azoospermia and fructose in CBAVD had been proved by many authors [5]. In this study, all 25 cases azoospermia without seminal fructose have been examined and proceed percutaneous epididymal sperm aspiration (PESA) by andrologist to find the infertility reason. The result shows that the reason in all the cases is CBAVD. Fructose concentration in obstructive azoospermia cases is lower than normal or absent [9]. By other side, In human with non-obstructive azoospermia, fructose concentration usually higher or equal than normal [9]. Inflammation of the reproductive glands causes temporary obstruction, so that sperm count and seminal fructose concentration may decrease, but rarely absence both of them [9,40,41].

Conclusion

Seminal fructose concentration of normozoospermia group is significant lower than oligozoospermia group. Fructose seminal concentration has negative correlations with sperm concentration, concentration and motility. 100% azoospermia cases without seminal fructose have been examined and proceed percutaneous epididymal sperm aspiration (PESA) by andrologist to find the infertility reason. The result shows that the reason in all the cases is CBAVD. Fructose concentration in obstructive azoospermia cases is lower than normal or absent [9].
