Introduction

Wounds are observed as common presentation of either minor or major injuries and their healing (a biological phenomenon) is the ultimate goal. It gets affected by a variety of factors like diabetes, old age, vascular compromise and smoking etc. converting the wound into a chronic one which draws world’s estimated 4% budgets for healthcare [1]. United States consumes an estimated $50 billion annually with an average of $3.00-$10,000.00 per wound [2]. The healing mechanism consists four phases supposed to occur in sequence of timeframe with appropriate duration and intensity for ideal wound healing these are:

a) Hemostasis (Platelet activation followed by release of substances initiating the coagulation process).

b) Inflammation (mediated by substances like prostaglandin, complement proteins and cytokines released at injured site responsible for chemotaxis of inflammatory cells including neutrophils followed by macrophages resulting into apoptosis and phagocytosis within 1-2 days following injury propelling the wound into next phase).

c) Proliferation (Activated macrophages liberate PDGF, TGF, EDF, FGF, and VEGF responsible for angiogenesis followed by...
accumulation of fibroblasts and macrophages resulting into the formation of granulation tissue consequent conversion of fibroblast into myofibroblast).

d) Remodeling (characteristics include apoptosis of endothelial cells, myofibroblasts, and macrophages leaving behind the extracellular matrix proteins while remaining fibroblasts and the macrophages get replaced by collagen and it lasts for 6-24 months) [3].

A wound may heal with any of the three types of the healing namely primary intention, secondary intention and tertiary intention.

   a) A wound Heals through primary intention when its edges are in close proximity to each other the best example is a surgical wound closed by staple or sutures characterized by minimal granulation tissue and scar.

   b) Ulcers heal by secondary intension where wound edges have a clear gap in between to be filled by granulation tissue taking a longer time.

   c) Tertiary intention wound healing is observed in infected wounds where there is a need of topical antimicrobial therapy over days that results into two granulation surfaces to be approximated later on with deeper, wider and prominent scar [4].

Healing is affected by certain systemic factors like age, gender, sex hormones, stress, diabetes, medication, alcoholism, smoking and nutrition as well as some local factors which include oxygenation, infection, foreign body, venous sufficiency, edema and raised local pressure like compartmental syndrome [5]. Such factors put the wound at risk of complications like keloid formation (excessive collagen production), hypertrophic scar (granulation tissue over produced), wound dehiscence (physical rupture) and wound contractures [6]. We explored the anti-inflammatory and wound healing potential of bentonite which contains montmorillonite as its principle constituent along with laumontite, illite, and non-argillaceous detrital minerals [7]. Clay minerals possess natural properties against organic and inorganic contamination that can be enhanced by their further modification [8].

The history of using clay by humans to achieve and maintain health is as old as (Aristotle 384-322 BC). People also used to eat clay (geophagy) for infections, GI inflammation and topical use of mud spas (pelotherapy) to adsorb skin toxins along with treating rheumatism [9]. The geophagy may be attributed to cultural and religious practices or psychological and nutritional disorders but medical practitioners consider it as an abnormal behavior termed as pica syndrome. Some researchers consider it as a process of adaptation in mammals and primates or a physiological response to iron and zinc deficiency [9]. The current study was planned to evaluate the wound healing effects of bentonite in rabbit model.

**Methodology**

Study was approved by ERC (Ethical review committee) Isra University. Rabbits were purchased from Hyderabad city under inclusion criteria (weight 1-3 kg, Healthy Rabbits of both genders) and exclusion criteria (underweight sick and pregnant rabbits). After acclimatization rabbits were given 4 cm longer cutaneous cut under aseptic surgical measures. Dressing was done with bentonite paste (purchased from local market and mixed with normal saline) on alternate days to observe the wound healing effects of bentonite. Wound size was measured with measuring tape while wound tissue placed in 10% formalin jars for histology slides preparation. The histological grading was done using H&E staining under light microscope by the pathologist of pathology department of the Isra University.

**Results**

Significant reduction in wound size was seen from the initial sizes (4.0±0.00 cm) to (3.90±0.47) after 3 days while the size at 7th (3.18±0.62 cm) and 13th days (1.01±0.01 cm) with statistically significance level of p-value 0.00007. Histological features showed reduced inflammatory reaction from +++ to ++ and + over week 1 and week 2 respectively. Fibroblast increased after 1st week and reduced at the end of 2nd week +++ to ++ while collagen contents increased after 2nd week in comparison to 1st week from ++ to +++ respectively showing wound healing (Tables 1 & 2) and (Figures 1-4).

Discussion

Inflammation is a physiological response from the body against the pathogens and macrophages play a big role through multiple cytokines production like TNF-α (tumor necrosis factor-α), IL-1α (interleukin-1 α), IL-1β (interleukin 1-β), IL-6 (interleukin 6) and NO (nitric oxide) [10]. Any agent that interferes with these mediators will reduce the inflammation. Clay was studied by many workers and found promising results Keith D. Morrison (2016) reported antibacterial effects of the clay against *E. coli* and *MRS* (methicillin resistant *Staphylococcus*) and attributed this activity of clay with its soluble reduced metals and expandable clay minerals that absorb cations, providing a capacity for extended metal release and production of toxic hydroxyl radicals. Fe$^{2+}$ and Al$^{3+}$ that synergistically attack multiple cellular systems in pathogens [11]. Lynda B. Williams (2011) also found antibacterial effects of clay against *E. coli* [12]. Complete eradication by clay has also been reported for *Staphylococcus aureus*, methicillin resistant *S. aureus* (MRSA), Escherichia coli, Pseudomonas aeruginosa and Salmonella typhi in published literature [13]. Another type of clay from British Columbia, Canada, Kisameet glacial clay has shown strong antibacterial action against *Enterococcus faecium*, Klebsiella, *Staph. aureus*, *Pseudomonas aeruginosa* and Acinetobacter baumannii, and anti-fungal activity against *Cryptococcus neoformans* and *Candida albicans* [14]. Shehab A Lafi (2011) also reported the Egyptian clay to be effective against *Pseudomonas aeruginosa* and *Staph. Aureus* [15].

Current experiments demonstrated bentonite to help in the healing process from reduction of inflammatory reaction to increased fibroblast migration. Wound healing was seen over two weeks with maximum collagen deposition on histological examinations. The exact mechanism for this aspect of bentonite is yet to be known but we observed intense reaction (inflammatory) was converted into moderate one after 1 week that further improved by bentonite to a very mild category at two weeks. Emami (2006) results also showed reduced inflammatory response to a significant level on treatment with Bentonite [16]. Angiogenesis, an important step in wound healing that enhances the circulation of blood to the injured area to facilitate oxygen and nutrients supply was also improved by Bentonite from 3rd day and onward. We could not evaluate the possible mechanisms involved in these anti-inflammatory and wound healing properties of bentonite due to our financial limitations that remained the weakness of our study. Bentonite may have some inhibitory effects on arachidonic acid break down pathways and cytokine involved in the inflammatory process that is what we recommend and plan to explore in the future.

Conclusion

Bentonite possesses strong anti-inflammatory and wound healing properties.
