Abstract

Objectives: To study the clinical characteristics and laboratory profile of systemic lupus erythematosus (SLE) in pediatric Patients at Hue Central Hospital of Vietnam.

Methods: Children presenting to our Pediatric Center with suspected SLE, fulfilling SLICC 2012 criteria for the diagnosis of SLE were reviewed retrospectively. The study period was from January 2017 to October 2018. The clinical presentation, laboratory parameters and histopathology were analyzed.

Results: A total of 21 patients fulfilled the SLICC 2012 criteria; there were 16 girls and 5 boys with a sex ratio of 1:3.2 favoring girls. The mean age on presentation was 13.24 ±1.411 years with a range of 10-16 years. The most common symptom was nephrotic damage 76.2%, acute cutaneous lupus 71.4%; nonscarring alopecia 66.7%, chronic cutaneous, synovitis 42.9%, hemolytic anemia 38.2%, oral or nasal ulcers 23.8%. Anti-dsDNA antibody positivity 85.7%, ANA positivity 81%. Lupus nephritis IV is the most common in 42.9%.

Conclusion: SLE in children has a wide range of presentations and complex progression so that a high index of suspicion should be maintained in order to make an early diagnosis is very necessary.

Keywords: Anemia; Systemic Lupus International Collaborating Clinics; Antinuclear Antibodies; Lupus Nephritis; Systemic Lupus Erythematosus

Introduction

Systemic lupus erythematosus (SLE) is an autoimmune condition characterized by multiorgan inflammation and autoantibodies production. The course of this disease is characterized by periods of flare and remission, and inflammation can result in irreversible tissue damage, as well as premature death [1]. The etiology remains poorly understood; however, genetic and environmental factors are involved in the pathogenesis [2]. Ten to twenty percent of cases are diagnosed in the first 2 decades of life with a peak incidence at 10-14 years with female predominance, the disease is rare in children below 5 years old [3,4]. It has been suggested that children with SLE had different signs and symptoms at onset and a more severe and aggressive disease course than adult patients [5-7]. There is no specific diagnostic test for cSLE, and diagnosis is notoriously difficult due to protean clinical symptoms and signs. The clinical manifestations of SLE have been extensively described from different geographical parts of the world, the prevalence and severity of the disease differs among ethnic groups [8-12]. The disease has variable presentations including conditional symptoms, cutaneous, cardiac, pulmonary, musculoskeletal and renal. The disease course is characterized by periods of remission and flares and children with SLE have more active disease at presentation and over time than do adults with SLE, especially active renal disease [13]. The aim of our retrospective study was to determine the clinical, laboratory characteristics and classification of lupus nephritis of childhood SLE in the center of Vietnam.

Patients and Methods

We reviewed the hospital records of children younger than 16 years of age who were diagnosed to have SLE at Pediatric Center
of Hue Central Hospital between January 2016 and October 2018. The diagnosis of SLE was made on the basis of the Systemic Lupus International Collaborating Clinics (SLICC) 2012 criteria [14]. All patients were reviewed retrospectively for demographic characteristics, clinical and laboratory variables.

We recorded the details of clinical signs, symptoms, and the various investigations performed such as complete hemogram, direct Coombs test, 24h urinary proteins. In the immunological tests, antinuclear antibodies (ANAs) and antibodies titer to double-stranded DNA (dsDNA) were measured using an indirect immunofluorescence test; ANA titer of more than 1: 40 and an anti-dsDNA antibody level of more than 55 IU/ml were considered positive. 7 patients underwent renal biopsy. Renal lesions were classified according to the World Health Organization classification (WHO) [15]:

i. Class II: pure mesangial proliferative LN;
ii. Class III: focal segmental proliferative glomerulonephritis LN;
iii. Class IV: diffuse glomerulonephritis LN and
iv. Class V: diffuse membranous glomerulonephritis LN.

Mixed class IV + class V and class III + class V was grouped as class IV and class III respectively. A second or even a third renal biopsy was in some cases indicated during the course of the disease. Specific histological features were assessed in each biopsy to give insight into activity and chronicity of lesions. All data were analyzed using IBM SPSS statistics v19, using adequate test and accepting P < 0.05.

A total of 21 pediatric patients, who fulfilled the SLICC 2012 diagnostic criteria, were included in this study. There were 5 males and 16 females at presentation with a sex ratio of 1:3.2 favoring girls. The average age at diagnosis was 13.24 ± 1.411 (range 10 – 16 years). The clinical manifestations of SLE are presented below. Most of these manifestations have been included as part of classification criteria for SLE, as a means of categorizing patients for study purposes. The most common clinical manifestations seen were acute or chronic cutaneous lupus in 81.0%, followed by renal disease in 76.2%, nonscarring alopecia in 66.7% and arthritis in 42.9% of patients. Other manifestations are listed in Table 1.

Among hematological manifestations, leukopenia was observed in 1 patients (4.8%), thrombocytopenia was observed in 3 patients (14.3%), and hemolytic anemia was observed in 8 patients (38.2%) (Table 2). The immunological parameters are show in Table 2. 81% of our patients had positive ANA titer. Anti-ds-DNA was positive in 85.7% of patients. Among 16 patients with renal disease, 7 of them had renal biopsy with histopathological evaluation classified according to modified world Health Organization classification (Table 3).

Discussion

This is a retrospective single center study carried out in Pediatric Center of Hue Central Hospital. The total number of SLE patients diagnosed in the period from January 2017 to October 2018 was 21 patients. This small number of patients may be due to that many pediatric SLE patients are followed by adult rheumatologist due to adolescent predilection of this disease. Therefore, Knowledge of general pediatric diseases that can mimic SLE is very important in making the accurate diagnosis. Age at onset ranged from 10-16 year with mean of 13.24 ± 1.411 years. In pediatric population, SLE is more common in adolescence than that in children under 5 years old. Our data was similar to other studies such as Hiraki with the average of age was 13.2 ± 3.17 years [16], Bader Meunier with the onset age at 11.5 ± 2.5 years [17]. According to Jebali et al. [18], about 15 to 20% of SLE starts in childhood. However, the exact prevalence of cSLE among the SLE population remains unknown.

In Egypt, several studies [19,20] have reported a relatively high prevalence of lupus in Egyptian children compared to Tunisian children. The disease was diagnosed before the age of 10 years in 17 % of patients. The majority of cSLE children were aged above 10 years [21,22]. Children with SLE are more susceptible than adults to nephritis [19,22]. In Arab countries, pediatric lupus nephritis was noted in 29 to 80% of cases [9,21]. In western countries, renal involvement was reported also in 30 to 80 % [23]. It affected females more than males and in our population with the female to male ratio was 3:2:1. This was consist to the report of Thabet Y [24]. In study of J Piette and B Wechsles showed that in 85% SLE patients was female at reproductive age. In the study of Jebali et
Al. [18] showed that, female to-male ratio was 9.75/1 while in the other reports, there was a lower predilection for female gender in childhood lupus [25,26]. The patients with SLE may present with various systemic manifestations. The most common clinical manifestation in our study was neurological damage 76.2%, acute cutaneous lupus 71.4%; nonscarring alopecia 66.7%, chronic cutaneous, synovitis 42.9%, hemolytic anemia 38.2%, oral or nasal ulcers 23.8%.

This shows that it is difficult to diagnose SLE based on clinical features only. The clinical diagnosis of SLE hinges on careful and very thorough assessment of the presenting clinical features, examination of all the organ systems and selected investigations. Symptoms often occur intermittently and cumulatively over many months and years. Oral ulcers, arthralgia, hair fall, Raynaud’s phenomenon, photosensitive rashes, pleuritic chest pains, headaches, fatigue, fevers and lymphadenopathy are just a few of the many non-specific presenting features of this disease. Clinical examination of all organ systems including routine urinalysis and blood pressure measurement is mandatory. Simple investigations may yield useful information. In the presence of suggestive clinical signs and symptoms, laboratory testing can support and confirm the diagnosis of SLE. A hallmark of SLE is the production of multiple autoantibodies. The commonest autoantibody is the antinuclear antibody (ANA), present in more than 95% of SLE patients.

In the presence of an ANA, it is appropriate to examine for specific autoantibodies including double-stranded DNA (dsDNA) and the extractable nuclear antigens (ENAs), recognizing that particular autoantibodies correlate with certain disease features [27]. The test for ANA has high sensitivity (>95%), but its specificity for SLE is as low as 36% [28]. Moreover, up to 10% of ‘healthy’ children will demonstrate a positive ANA. In SLE, anti-dsDNA antibodies have high specificity. In our study, 81% of our patients had positive ANA titer and Anti-dsDNA was positive in 85.7% of patients which is similar to other studies [29]. In our study. The most frequent histopathological finding was class IV LN (42.9%), approaching the results from several reports, ranging from 37% to 46% [30, 31]. Class V LN has been reported to have a lower incidence in children [32]. In our group, pure class V LN was found only in 14.3% of cases.

Conclusion

In conclusion, lupus nephritis is rare in children. SLE in children has varied clinical and laboratory presentations depending on the major organs involved. Any child with multisystem involvement, prolonged unexplained fever and atypical clinical manifestations should be evaluated for SLE. Renal biopsy can be done in all patients to detect earlier silent involvement, of kidney.
