Cleft palate is one of the most frequent anomalies in the head and neck region. Different treatments have been used but with each, there are still some disadvantages such as fistulas. The use of a 3D scaffold, with osteoinductive properties, from an easily accessible source, such as dental pulp stem cells, should improve and shorten the treatment of a cleft palate. We conducted a pilot study, in a Vietnamese pig, to evaluate the effectiveness of treating a critical defect of the palate bone, with a 3D Polycaprolactone (PCL) scaffold, in combination with a Beta Tricalcium Phosphate powder (β-TCP) and Pig Dental Pulp Stem Cells (pig DPSC) obtained from the subject pig.

**Keywords:** Dental Pulp Stem Cells; 3D Scaffold Cleft Palate Regeneration

This is due to the amount of implanted tissue or other factors but whatever the reason is, literature reports that after the treatment palatal wound dehiscence, a residual fistula has an estimated occurrence ranging from 3.4 to 27% [6] and other percentages [7,8]. With the advent of scaffolds printed in three dimensions (3D) [9], we can perhaps overcome those deficiencies. Scaffolds made by a 3D printer, having a microenvironment in three dimensions, may favor the comfort of cells, their survival and proliferation. In this paper the potential of pig dental pulp stem cell in combination with 3D scaffolds for becoming a choice for cleft palate defects treatments is examined in an *in vivo* model.
Materials and Methods

Scaffolds Manufacturing

The Polycaprolactone (PCL) used in this project was directly provided as a 1.75 ± 0.005 mm filament for standard 3D printers (3Dmakers.com, Mw: 84500 ± 1000, 100% pure, Haarlem, Netherlands). For the fabrication of the scaffolds, a Hephestos 2 (Prusa i3 - BQ, Madrid, Spain) with a heated bed was used. The extruder was a double drive gear, with a nozzle of 400 μm.

In Vivo model

A male Vietnamese pig subtype was approved by the ethical committee (CE/FESI/052017/1174) for the pilot study. Central and lateral lower incisors were extracted to isolate the stem cells. The pulp was cut into small pieces and treated with 0.05% collagenase (Sigma Aldrich, USA) and low glucose Dulbecco’s modified Eagle Medium (DMEM) (Bio-west, México) and incubated at 37°C for 20 minutes. After the collagenase inactivation, the cell suspension was centrifuged at 350g for 5 min, the cell pellet was cultured with low glucose Dulbecco’s modified Eagle Medium (DMEM) (Bio-west, México), supplemented with 10% Fetal Calf Serum (FCS) (Bio-west, México) and 1% penicillin–streptomycin (Sigma Aldrich, USA), and incubated at 37°C in an atmosphere of 5% CO₂ until the cells reached 80% confluence. The culture media was changed every third day. The third passage was used for the following test and for the implantation in vivo.

Immunophenotype of Pig Dental Pulp Stem Cells

The pig dental pulp stem cells phenotype was analyzed by flow cytometry, utilizing the following antibodies, coupled to fluorophores CD90-FITC, CD105 VB421. Previously, harvested stem cells were seeded in 6 wells plates, when the cells reached 80% confluence were placed in 1.5 ml eppendorf tubes, centrifuged at 600g. The cellular pellet was washed with phosphate buffer saline (PBS) supplemented with 2% of fetal calf serum and centrifuged again at 600g for 5 minutes. The cells were then resuspended in a 400 μl volume of PBS, supplemented with 2% FCS. before 0.3 μl of the two coupled antibodies were added without dilutions and then incubated for 15 min at room temperature before being read using the CytoFLEX LX flow cytometer (BRVYNI), selecting the corresponding filters for the detection of each of the fluorochromes with 10,000 events being captured for each sample. Pig dental pulp cells, without coupled antibodies, were used as controls.

Scaffold Sterilization and Seed of the Pig Dental Pulp Stem Cells

The 3D scaffold (Figure 1) was sterilized with ethanol at 70%, and then left in a physiological solution with antibiotic and antifungal properties for 24 hours. After this time it was placed in UV radiation for an additional 24 hrs, before the pig’s dental pulp stem cells were planted in layers. First a layer, with 300 thousand cells, was placed in the scaffold, then a layer of Beta Tricalcium Phosphate powder (β-TCP) (R.T.R granules, Septodont, France) was added, thus 5 layers of each component were applied. The construct (3D scaffold + pig DPSC + β-TCP) was incubated for 48 hrs, before the surgery. The pig was anesthetized and a defect of 10 mm was created in the left side of the maxilla (Figure 2), the construct was placed in the defect (Figure 3) and sutured with vicryl three zeros. After 6 months the pig was euthanized and the maxilla was removed. An occlusal X-ray was taken before the maxilla was subsequently placed in 4% formalin for histological analysis.

Figure 2: A defect of 10 mm was created in the left side of a male Vietnamese pig maxilla.

Figure 3: The construct (3D scaffold + pig DPSC + β-TCP) was placed in the defect of a male Vietnamese pig maxilla.
Results

It was possible to cultivate the pig’s dental pulp stem cells by means of enzymatic digestion. The first cells proliferated were between days 2 through 4, which showed elongated fibroblast-like cells (Figure 4). Cultures reached 80-90% confluence around day 14. The phenotype pig dental pulp stem cell were 91.0% positive for antibody CD 90 and 80.0% to antibody CD 105 (Figure 5) Animal welfare was supervised by the University’s veterinarians. The pig was fed a soft diet for the first week so there would be no problems chewing. There were no signs of infection after the surgery not through the experiment’s end point at 6 months, when euthanasia was practiced in accordance to the principles of minimal pain and/or distress to the pig. Radiographically, we can see that almost entire defect closed in the yellow circle (Figure 6). This regeneration could be confirmed with computed tomography and histological analysis.

Conclusion

Stem cells from dental pulp are easy to obtain while also having the capacity to proliferate quickly. The use of 3D scaffolds, with osteo-receptor properties, helps to induce the regeneration of good quality bone in both the short and medium term.
