Keywords: Smoking Prevalence; Smoking Intensity; Secondhand Smoking; Changes of Smoking Behavior

ABSTRACT

Objective: To study changes in the prevalence and intensity of tobacco smoking among population in relation to gender and age, to evaluate effect of the tobacco control measures which were provided by the anti-smoking law in 2013.

Material and Methods: The population-based survey of the sample of Moscow adult population was conducted in 2017 - 2018. The sample size is 1020 people, aged 18 - 81 years. The unified questionnaire in relation to smoking behavior and anamnesis was used by trained interviewers. To study the dynamics of smoking behavior among the population current smoking patterns and attitudes were compared with the result of previous similar surveys conducted before 2013.

Results: Overall, the percentage of current smokers in the entire sample was 37.9 %, former smokers who quit smoking more than a year ago - 25.5% and never smoking - 36.6%. The smoking prevalence among the men decreased from 61.2% (1996-1997) to 54.2% (2017-2018), $p < 0.001$, and among women increased from 16.1% (1996-1997) to 27.3% (2017 - 2018), $p < 0.0001$. Among smokers of the sample surveyed in 2017-2018 the percentage of intensive smokers (≥ 20 cigarettes a day) was 22.0% among men and 4.1% among women. In the sample of smokers surveyed in 2010-2012 the percentage of intensive smokers was significantly higher, 46% of men and 25% of women, $p < 0.001$. Out of 633 nonsmoking respondents 60,5% reported having episodes of passive exposure to tobacco smoke from the environment.

Conclusion: Despite some reduction in tobacco consumption among the population, the prevalence of TS in Russia remains one of the highest in the world. The number of current smokers among Moscow population comprises more than a third of the adult population. Fight against the tobacco epidemic requires a long-term and relentless application of the entire complex of the anti-smoking measures aimed to prevent and to stop smoking and to reach more results in decreasing smoking prevalence among population.

Introduction

The tobacco epidemic causes enormous damage to the health of the population, especially in countries with the highest prevalence of tobacco smoking (TS), to which Russia belongs [1]. TS is one of the leading modified causes of the wide-spread chronic, noncommunicable diseases, which most often lead to disability and premature mortality [2]. It is estimated that TS is the cause of more than 17% of all deaths in Russia [3]. The prevalence of TS among the population, as well as the nature of smoking behavior of individuals can change significantly with time, primarily as a result

of certain measures to protect the population from the spread of TS. There are effective measures to combat the tobacco epidemic, which were recommended in the WHO Framework Convention on Tobacco Control [2] and which are taken as a basis for the formation and adoption of the Federal law of the Russian Federation "On protection of public health from the effects of surrounding tobacco smoke and the consequences of tobacco consumption" [4]. The law was approved in 2013. One of the main conditions for the successful implementation of a set of measures to prevent and eliminate TC is

the monitoring of tobacco consumption, based on regular surveys of the population with an objective assessment of the smoking status and the main indicators of smoking behavior.

Material and Methods

Population-based survey of the sample of Moscow adult population who underwent medical check-up examination in municipal out-patient clinics, was conducted in 2017 - 2018. The sample size is 1020 people, aged 18 - 81 years. Median age - 54, mean age - 51, 71+14, 27. The 23-item unified questionnaire in relation to smoking behavior and anamnesis was used by trained interviewers. To study the dynamics of smoking behavior among the population current smoking patterns and attitudes were compared with the result of previous similar surveys conducted before 2013. The statistical analysis system was used.

Results

Overall, the percentage of current smokers in the entire sample was 37.9 %, former smokers who quit smoking more than a year ago - 25.5% and never smoking - 36.6%. The percentage of current smokers was 54% among men and 27.3% among women ($p < 0.001$). Historical comparison of this data on the prevalence of TS with the results of a similar survey concerning the smoking status of more than 4,000 residents of Moscow aged 20-80 years in 1996-1997, shows that the smoking prevalence among the men decreased from 61.2% (1996-1997) to 54.2% (2017-2018), $p < 0.001$, and the prevalence of TS among women increased from 16.1% (1996-1997) to 27.3% (2017 - 2018), $p < 0.0001$. In the present study women smoking prevalence rate was the highest in young age group 18-30 years - 45,2% and almost three times lower in the older age group ≥ 50 years - 17,0% ($p < 0,05\%$). For men the highest smoking rate was in middle age group 30-49 years - 65,7%.

The smokers were considered to be intensive smokers if they smoked more than 20 cigarettes a day. Among smokers of the sample surveyed in 2017-2018 (387 persons) the percentage of intensive smokers was 22.0% among men and 4.1% among women. In the sample of smokers, comparable in age and place of residence, surveyed in 2010-2012 (507 persons), the percentage of people smoking more than 20 cigarettes a day, was significantly higher, 46% of men and 25% of women, $p < 0.001$.

A significant majority of the current smokers - 74.8% of men and 81.1% of women reported having at least one quit attempt in the past. These attempts were without any result for majority of smokers but some of them achieved definite results. Historical comparison of samples of smokers surveyed in different years showed an increase in the percentage of people with effective attempts to stop smoking for a week and more in samples of smokers surveyed in later years. So, in the sample of smokers surveyed in 1998 -2000, 2010-2012 and 2017-2018 years among the smokers who tried in the past to quit respectively 24.8%, 48.9% and 60.4% persons could stop smoking for a week or more ($p < 0,01$).

In the present study of the 633 nonsmoking respondents 60,5% reported having episodes of passive exposure to tobacco smoke from the environment with a total duration of all episodes of exposure to tobacco smoke during a week of 30 minutes or more. According to Global surveys of the Russian population in 2009 and 2016 [5,6], secondhand smoking significantly decreased at home (34.7% in 2009 and 23.1% in 2016), in working places (34.9% in 2009 and 21.9% in 2016), in various public places (17.0% in 2009 and 3.6% in 2016). Out of current smokers in the last our survey 3.8% men and 0.6% woman smoked hookah. 11 persons reported using of e-cigarette, all of them from the younger age group up to 30 years (77 persons). It was found in other survey that the prevalence of hookah smoking in Russia has increased significantly during the last 10-15 years and currently about 2.8% of the adult population (4.1% of men and 1.7% of women) smoke hookah [6].

Conclusion

The study results confirm a marked decline of TS prevalence, especially among men in recent years in Moscow population. Also, the percent of heavy smokers (≥ 20 cigarettes daily) significantly decreased among current smokers. The increase in the effectiveness of attempts to quit TS was also established, which is probably due to the organization in the health service of qualified assistance in smoking cessation. All these positive changes are primarily associated with the implementation since 2013 of a complex of measures indicated in the Russian antismoking law [4]. Despite some reduction in tobacco consumption among the population, the prevalence of TS in Russia remains one of the highest in the world. In the present study the number of current smokers among Moscow population comprises more than a third of the adult population. Fight against the tobacco epidemic requires a long-term and relentless application of the entire complex of educational, administrative, medical and economic measures aimed to prevent and to stop smoking and to reach more results in decreasing smoking prevalence among population.
